(57) **ABSTRACT**

A source element for generating seismic waves includes a housing; a partitioning element placed inside the housing and configured to split the housing in a closed chamber and an opened chamber; and a valve in fluid communication with the closed chamber and configured to supply high-pressure air to the closed chamber to make the partitioning element oscillates. An oscillation of the partitioning element generates low-frequency seismic waves.

## METHOD AND SYSTEM FOR LOW-FREQUENCY PRESSURIZED SOURCE

### BACKGROUND

#### 1. Technical Field

Embodiments of the subject matter disclosed herein generally relate to methods and systems and, more particularly, to mechanisms and techniques for increasing low-frequency content of seismic energy generated by a marine seismic source array.

#### 2. Discussion of the Background

Reflection seismology is a method of geophysical exploration to determine the properties of a portion of a subsurface layer in the earth, information that is especially helpful in the oil and gas industry. Marine reflection seismology is based on the use of a controlled source that sends energy waves into the earth. By measuring the time it takes for the reflections to come back to plural receivers, it is possible to estimate the depth and/or composition of the features causing such reflections. These features may be associated with subterranean hydrocarbon deposits.

For marine applications, a seismic survey system **100**, as illustrated in FIG. 1, includes a vessel **102** that tows plural streamers **110** (only one is visible in the figure) and a seismic source **130**. Streamer **110** is attached through a lead-in cable (or other cables) **112** to vessel **102**, while source array **130** is attached through an umbilical **132** to the vessel. A head float **114**, which floats at the water surface **104**, is connected through a cable **116** to the head end **110A** of streamer **110**, while a tail buoy **118** is connected, through a similar cable **116**, to the tail end **110B** of streamer **110**. Head float **114** and tail buoy **118** are used, among other things, to maintain the streamer's depth. Seismic sensors **122** are distributed along the streamer and configured to record seismic data. Seismic sensors **122** may include a hydrophone, geophone, accelerometer or a combination thereof. Positioning devices **128** are attached along the streamer and controlled by a controller **126** for adjusting a position of the streamer according to a survey plan.

Source array **130** has plural source elements **136**, which are typically air guns. The source elements are attached to a float **137** to travel at desired depths below the water surface **104**. During operation, vessel **102** follows a predetermined path **T** while source elements (usually air guns) **136** emit seismic waves **140**. These waves bounce off the ocean bottom **142** and other layer interfaces below the ocean bottom **142** and propagate as reflected/refracted waves **144**, which are recorded by sensors **122**. The positions of both source elements **136** and recording sensors **122** may be estimated based on GPS systems **124** and recorded together with the seismic data in a storage device **127** onboard the vessel. Controller **126** has access to the seismic data and may be used to achieve quality control or even fully process the data. Controller **126** may also be connected to the vessel's navigation system and other elements of the seismic survey system, e.g., positioning devices **128**.

A source element may be impulsive (e.g., an air gun) or vibratory. A vibratory source element is described in U.S. patent application Ser. No. 13/415,216 (herein the '216 application), filed on Mar. 8, 2012, and entitled, "Source for Marine Seismic Acquisition and Method," assigned to the same assignee as the present application, the entire content of which is incorporated herein by reference.

Presently, the air gun is the work horse of marine seismic acquisition. However, neither air guns nor existing vibratory source elements are effective in the low-frequency range of

2

the spectrum, mainly in the 1 to 10 Hz range. In other words, energy generated by an air gun in the low-frequency spectrum is too weak to be reflected to seismic receivers to be recorded. The low-frequency energy range is useful in seismic exploration because it provides better seismic energy depth penetration, which is extremely valuable for imaging complex geological settings, such as sub-salt, basalt, chalk or even dense carbonate. New processing methods, such as full wave inversion (e.g., a data-fitting procedure based on full-wave-field modeling to extract quantitative information from seismic data) can benefit greatly from increased energy in the low-frequency range.

Thus, there is a need to obtain the low-frequency range to better interpret seismic data. To be able to record such data, source arrays need to be adjusted/modified to generate low-frequency content. Therefore, it is desirable to provide source elements and methods capable of generating low-frequency energy.

### SUMMARY

According to one exemplary embodiment, there is a source element including a housing; a partitioning element placed inside the housing and configured to split the housing in a closed chamber and an opened chamber; and a valve in fluid communication with the closed chamber and configured to supply high-pressure air to the closed chamber to make the partitioning element oscillates. An oscillation of the partitioning element generates low-frequency seismic waves.

According to another embodiment, there is a method for generating low-frequency seismic energy. The method includes deploying in water a source element that includes a housing split into a closed chamber and an opened chamber by a partitioning element; supplying compressed air to the closed chamber so that the partitioning element moves toward the opened chamber; generating low-frequency seismic waves by moving the partitioning element; and venting the closed chamber for returning the partitioning element.

According to yet another embodiment, there is a source element that includes a housing having an open end freely communicating with seawater and a closed end configured to hold air; a valve that communicates with the closed end; and a controller connected to the valve and configured to supply compressed air such that an air-water interface formed inside housing moves toward the open end and also configured to remove the compressed air from the closed end so that the air-water interface moves toward the closed end. A movement of the air-water interface generates low-frequency seismic waves.

According to still another embodiment, there is a method for generating low-frequency seismic energy. The method includes deploying in water a source element having an open end and a closed end, the open end being configured to allow the water to partially enter inside a housing of the source element; increasing an air pressure at the closed end so that an air-water interface moves toward the open end; generating a seismic wave by moving the air-water interface; and venting out the compressed air from the closed end for displacing the air-water interface toward the closed end.

### BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate one or more embodiments and, together with the description, explain these embodiments. In the drawings:

3

FIG. 1 is a schematic diagram of a seismic acquisition system;

FIGS. 2 and 3 are schematic diagrams of a source array having low-frequency and high-frequency source arrays;

FIG. 4 is a schematic diagram of a source element configured to emit low-frequency energy;

FIG. 5 is a flowchart of a method for actuating the source element illustrated in FIG. 4;

FIG. 6 is a schematic diagram of another source element configured to emit low-frequency energy;

FIG. 7 is a flowchart of a method for actuating the source element illustrated in FIG. 6;

FIG. 8 is a schematic diagram of a variation of the source element illustrated in FIG. 6;

FIGS. 9A-D are graphs illustrating various characteristics of a low-frequency source element;

FIG. 10 is a flowchart of a method for processing seismic data acquired with a low-frequency source element; and

FIG. 11 is a schematic diagram of a control device for implementing methods as noted above.

### DETAILED DESCRIPTION

The following description of the exemplary embodiments refers to the accompanying drawings. The same reference numbers in different drawings identify the same or similar elements. The following detailed description does not limit the invention. Instead, the scope of the invention is defined by the appended claims. The following embodiments are discussed, for simplicity, with regard to the terminology and structure of a source element configured to generate low-frequency acoustic energy in a marine environment. However, the embodiments to be discussed next are not limited to a marine source element; they may be applied to source arrays (i.e., to a collection of source elements) or even to land sources.

Reference throughout the specification to “one embodiment” or “an embodiment” means that a particular feature, structure or characteristic described in connection with an embodiment is included in at least one embodiment of the subject matter disclosed. Thus, the appearance of the phrases “in one embodiment” or “in an embodiment” in various places throughout the specification is not necessarily referring to the same embodiment. Further, the particular features, structures or characteristics may be combined in any suitable manner in one or more embodiments.

According to an embodiment, a source element is configured to generate low-frequency seismic energy to improve the low-frequency spectrum of a source array. The output of various low-frequency source elements can fill in the energy often lacking in conventional marine surveys where air gun sources are used. In one application, various low-frequency source elements are presented, each of which outputs low-frequency energy over a given portion of the low-frequency range of frequencies of interest. The low-frequency range of frequencies is mainly considered to extend from 1 Hz up to about 10 Hz. Above 10 Hz, existing air gun sources provide adequate source strength.

When implemented in an actual seismic survey system, a seismic source array 200 having one or more of the novel source elements to be discussed next may have, as illustrated in FIG. 2, two high-frequency sub-arrays 202 and a single low-frequency sub-array 204 that are towed by a vessel 201. In one application, all the sub-arrays are towed below the water line WL. Other configurations for the sub-array may be possible. Each sub-array may have plural source elements. In one application, the high-frequency sub-arrays 202 are towed

4

at a depth of about 5 m, while the low-frequency sub-array 204 is towed at a depth of about 25 m.

A side view of a marine acquisition system 306 that includes high-frequency seismic sources 302A (e.g., air guns) and low-frequency seismic sources 304A (to be discussed later) is illustrated in FIG. 3. System 306 includes towing vessel 301 that tows source array 300. Source array 300 may include, as discussed with regard to FIG. 2, one or more high-frequency sub-arrays 302 positioned at a depth H1 below the water line and one or more low-frequency sub-arrays 304 positioned at a depth H2 below the water line, where H2 is deeper than H1. Depth controllers 310 may be located on or next to each sub-array for maintaining a desired depth. Umbilicals 311 connect each sub-array to vessel 301. An umbilical may include a strength member, command and data capabilities, electrical power and pneumatic air supply.

Mechanical interface 312 connects corresponding umbilical components to pneumatic supply system 314, power supply system 316, and command and control device 318. Command and control device 318 may include a processing unit, as described later, that is capable of receiving and processing seismic data for imaging the surveyed subsurface. Command and control device 318 may also be configured to control the seismic source array's trajectory, adjust its trajectory and control the shooting of the source elements. Command and control device 318 may interact with the vessel's navigation system.

Although FIG. 3 shows each sub-array having a horizontal distribution, note that multi-level source sub-arrays (i.e., source elements distributed along a curved line or a variable-depth line) may be used instead of horizontal source sub-arrays 302 and/or 304. The above embodiments were discussed without specifying the type of seismic receivers used to record seismic data. In this sense, it is known in the art to use, for a marine seismic survey, streamers towed by one or more vessels, and the streamers include seismic receivers that may include hydrophones, geophones, accelerometers, other particle motion sensors, electro-magnetic sensors or a combination thereof. Also, the streamers on which the receivers are distributed may be horizontal, slanted or have a curved profile as disclosed, for example, in patent application Ser. No. 13/464,149, the entire content of which is incorporated herein by reference. In one application, the receivers may be distributed on autonomous underwater vehicles, on ocean bottom cables or other platforms.

In one application, sub-arrays 302 are configured to generate frequencies between about 10 and 200 Hz, while sub-array 304 is configured to generate frequencies between about 0.1 to 10 Hz. The source elements of these sub-arrays may be activated using a flip-flop scheme, a continuous scheme or any other known scheme. Next, various embodiments are discussed with regard to novel low-frequency source elements.

In one embodiment, a low-frequency source element 400 is illustrated in FIG. 4. Low-frequency source element 400, also called a pneuma-acoustic projector. Source element 400 has a housing 401 that extends along a horizontal axis X, which is substantially perpendicular to gravity Z. Source element 400 is designed to be towed horizontally to reduce drag. A tow cable 425 connects the vessel (not shown) to a fastener 419, which is fixedly attached to nose 401A of housing 401. Nose 401A may be shaped to reduce drag during towing.

Housing 401 includes a closed chamber 409 and an opened chamber 411. Closed chamber 409 does not communicate with the ambient water, and for this reason is called “closed,” while opened chamber 411 communicates with the ambient water and for this reason is called “opened.” The two cham-

5

bers are separated by a partitioning element **407**, which may be a flexible member having its perimeter (or circumference) fixedly attached to the housing **401**, or may be a movable piston, a movable part or a means for separating. If partitioning element **407** is a flexible member, e.g., a diaphragm or membrane, or a piston, two stopping elements **413** and **415**, e.g., screens, may be located in the closed and opened chambers, respectively, to limit movement of the partitioning element **407**.

Opened chamber **411** communicates with ambient **420** through one or more openings **417** located at the tail end **401B** of housing **401**. The ambient **420** may be considered to be the marine ambient. Openings **417** may be disposed circumferentially around the tail end **401B** of housing **401**. Housing **401** may be cylindrical or have other shapes.

A valve **403** may be housed within nose **401A**. Valve **403** may be fluidly connected to a supply line **421** and to a low pressure source **427** through a vent line **423**. Low pressure source **427** may be the atmospheric pressure or a low pressure reservoir that has air pumped out of it continuously. Supply line **421** may be connected to a compressed air source **422**, located on the vessel or on the source array. Vent line **423** may be also connected to the vessel or made to fluidly communicate with the environment. A controller **405** may be located in nose **401A** of the housing and is configured to control valve **403**. Valve **403** may be an a servovalve, an electro-pneumatic valve, e.g., a three-way valve or a three-way spool valve, or two individual proportional valves with one variable orifice used for introducing high-pressure air supplied through supply line **421** into closed chamber **409**. A second variable orifice may be used for venting the air from closed chamber **409** through exhaust hose **423**. Valve **403** fluidly communicates with closed chamber **409** through passage **410**. In one application, valve **403** may be either a direct drive type or may have a pilot valve (not shown) to drive the main valve.

Controller **405** is in communication with the vessel and data acquisition system via power and communication cable **429**. Controller **405** is also in communication with valve **403** and is configured to control this valve. When valve **403** is controlled to make supply line **421** fluidly communicate with closed chamber **409**, compressed air **431** is supplied inside closed chamber **409** and pressurized. Partitioning element **407** is then driven toward opened chamber **411**, causing water **432** inside the opened chamber to be forced out of it. The water passes through stopping element **415** and exits through openings **417**. By allowing the water to exit radially through openings **417** rather than axially, the reaction forces tend to be cancelled out, which reduces the vibration of source element **400**. Diverter **427** closes one end of opened chamber **411**, and it may be shaped to steer radially the exiting or entering water. Diverter **427** is shown having a round shape in FIG. 4. However, diverter **427** may have different shapes as long as the water volume exiting or entering the opened chamber is diverted along directions substantially perpendicular to longitudinal axis X. Alternatively, a means for diverting may be used for diverting the water volume as noted above.

To reduce the pressure inside closed chamber **409**, valve **403** is instructed to close the valve inlet orifice and open the exhaust orifice so the air located inside closed chamber **409** is now in communication with vent line **423**. As the air is exhausted, partitioning element **407** moves to the left in FIG. 4. First and second stopping elements **413** and **415** allow the air, but not partitioning element **407**, to pass.

A method for actuating source element **400** is now described with regard to FIG. 5. In step **500**, the source element is deployed in water. In step **502**, controller **405** instructs valve **403** to fluidly connect closed chamber **409** with supply line **421** so that compressed air is supplied inside the closed chamber. As a consequence of the increased pressure inside closed chamber **409**, partitioning element **407**

6

moves toward opened chamber **411**, partially pushing the water volume inside the opened chamber outside housing **401**. Seismic waves **440** may be symmetrically generated around housing **401** in step **504**. Excess air from closed chamber **409** is now removed through vent line **423** in step **506**, also under the instruction of controller **405**. Controller **405** may be programmed to supply and remove the air from closed chamber **409** with a desired frequency, so that seismic waves generated by the partitioning element's back and forth movement have a low-frequency. This action is achieved by instructing valve **403** to fluidly connect vent line **423** with closed chamber **409**. Due to this step, partitioning element **407** moves back toward its original position. Note that the initial pressure inside the closed chamber, i.e., before supplying compressed air, may be the ambient pressure so that similar pressures are on both sides of partitioning element **407**. The above cycle may then be repeated if a condition determined in step **508** is met, i.e., a time period for generating seismic waves is smaller than a predetermined period of time. If the condition is not met, the process advances to step **510** and stops.

The amount of compressed air and/or its pressure are source-dependent and also depend on the estimated locations of the target subsurface, and various optimization studies need to be performed to determine these parameters. In one application, plural source elements **400** are grouped together to form the low-frequency source sub-array **304** illustrated in FIG. 3. In another embodiment, traditional low-frequency source elements **200** are combined with one or more of the novel source elements of FIG. 4 to form sub-array **304**. In one embodiment, the source elements are attached to a common float to maintain them at predetermined depths. However, it is possible to tow the source elements without the float.

Another low-frequency source element is now described with regard to FIG. 6. Source element **600** has a housing **602** with an open end **602A** that directly communicates with environment **604**, usually seawater, and a closed end **602B**. A valve **606** is attached to housing **602** and fluidly communicates with an interior **608** of housing **602**. Valve **606** may be similar to valve **403** discussed with regard to FIG. 4, which acts as a flow control proportional valve or a combination of valves may be used: for example, a servovalve configured to act as a pressure control valve or still another possibility would be utilization of separate solenoid activated valves with one for pressurization and another for venting. Valve **606** may be controlled by a local controller **610**. In one application, valve **606** is a three-way valve, having a first position that communicates interior **608** with a high-pressure source **620**, a second position that communicates interior **608** with a low-pressure source **622**, and a third position in which interior **608** is insulated, i.e., the valve is shut. In one application, high-pressure source **620** may be an accumulator. The accumulator may have a volume of about 5 liters (l) and a pressure of about 14 MPa. High-pressure source **620** may be connected through a supply line **624** to a compressor (not shown) located on a towing vessel and may receive high-pressure air from the vessel. Low-pressure source **622** may be a low-pressure accumulator, having, for example, a volume of about 700 l and a pressure of about 0.1 MPa. Low-pressure source **622** may communicate with the ambient through a vent pipe **624**. In one embodiment, low-pressure source **622** is just a compartment in housing **602**. The low- and high-pressure sources may be located close to the source element. In one application, both sources are located on housing **602**. In another application, both sources are attached to a float of the source sub-array.

When in use, source element **600** generates seismic waves as now discussed with regard to FIG. 7. Source element **600** is deployed in water in step **700**. Water **604** partially enters housing **602** and a water-air interface **630** is formed, with air being present above interface **630** and water below. In other

words, a length of the inside of housing 602 is H and a length of the water column inside the housing is h. The air pressure above the interface is balanced out by water pressure below. Valve 606 is in the shut position. In step 702, valve 606 is controlled by controller 610 to fluidly communicate inside 608 with high-pressure source 620 to increase the air pressure. This pressure increase forces interface 630 away from valve 606, forcing water volume inside the housing to oscillate, which in turn generates seismic waves 634 in step 704. Controller 610 then changes a state of valve 606 so that inside 608 is in fluid communication with low-pressure source 622 in step 706. Thus, the pressure of inside 608 decreases until interface 630 returns to its initial position of step 700. Controller 610 may be programmed to supply and remove air from inside 608 with a desired frequency, so that seismic waves generated by the movement of the air-water interface back and forth have a low frequency. In other words, alternately supplying and removing compressed air from closed end 602B generates low-frequency waves. In step 708 a determination is made whether to continue to generate seismic waves. If this determination is yes, the process returns to step 702 to continue generating seismic waves. If the determination is no, the process advances to step 710 and stops. The determination may include a timer that times out after a predetermined amount of time, at which instant the result of the determination is "NO."

In one application, an area of open end 602A is about 1 m<sup>2</sup>. For such a large opening, and because water column displacement may be large, for example, about 0.5 m, it may not be feasible to use a flexible member at interface 630 for separating air from seawater. Thus, there is a possibility that seawater may come into contact with the interior of valve 606 and low-pressure source 622. This means that these parts need to be non-corrosive, or a barrier needs to be put in place to prevent seawater from touching these parts. According to an embodiment illustrated in FIG. 8, a barrier 860 is provided at the air-water interface. Barrier 860 may have its perimeter shaped to match a stopping member 862, which is fixedly attached to an inside of housing 802. Barrier 860 may be a float that floats in water so the presence of water makes the float move upward, along the Z direction, opposite gravity. Once barrier 860 contacts stopping member 862, it stops and creates a seal around its perimeter so that seawater cannot move past the barrier. A barrier guide mechanism 864 is configured to guide the barrier along the Z direction. The barrier guide mechanism may be a pole in one embodiment, and barrier 860 may have a hole for receiving the pole.

Controller 610 or 810 may be programmed to open and close valve 606 or 806 to cause the source element to emit a damped sinusoid at the desired frequency and desired damping rate. Note that controller 610 or 810 controls positive acceleration of the air-water interface (or water column) by allowing high-pressure air to enter the housing, and creates a negative acceleration of the interface (or water column) by venting out the high-pressure air.

According to one embodiment, assuming that H is about 1.4 m, h is the initial height of the water column and is about 0.7 m, the internal diameter of housing 602 being about 1.13 m, an intake orifice area is about 0.002 m<sup>2</sup>, an exhaust orifice area is about 0.024 m<sup>2</sup>, and a target of energy spectral density (ESD) is about 200 dB, the results illustrated in FIGS. 9A-D are obtained. FIG. 9A illustrates water column acceleration, FIG. 9B illustrates water column displacement, FIG. 9C illustrates ESD, and FIG. 9D illustrates pressure inside the housing versus time. Note the 3.5 Hz resonance frequency 900 in FIG. 9C.

In one application, plural source elements 600 are used in a source array, with a subset of them configured to emit in the 2-4 Hz range with a resonance at 3 Hz, and another subset configured to emit in the 4-8 Hz range with a resonance at 5

Hz. These numbers are exemplary and are not intended to limit the applicability of the embodiments. In other words, plural source elements 600 may be grouped in various ways to cover different frequency ranges with a resonance frequency inside each range. In one application, each source element 600 has a single resonance frequency.

Seismic data generated by the seismic sources discussed above and acquired with the streamers also noted above may be processed in a corresponding processing device for generating a final image of the surveyed subsurface as discussed now with regard to FIG. 10. For example, the seismic data generated with the source elements as discussed with regard to FIGS. 4, 6 and 8 may be received in step 1000 at the processing device. In step 1002, pre-processing methods are applied, e.g., low pass filtering to separate out the low frequency data set from the conventional seismic, demultiple, signature deconvolution, trace summing, motion correction, vibroseis (method of vibrating an element of a source for generating a seismic signal) correlation (might use this as an alternative to low pass filtering to remove data that was generated by a marine vibrator), resampling, etc. In step 1004, the main processing takes place, e.g., deconvolution, amplitude analysis, statics determination, common middle point gathering, velocity analysis, normal move-out correction, muting, trace equalization, stacking, noise rejection, amplitude equalization, etc. In step 1006, final or post-processing methods are applied, e.g. migration, wavelet processing, seismic attribute estimation, inversion, etc., and in step 1008 the final image of the subsurface is generated.

An example of a representative processing device capable of carrying out operations in accordance with the embodiments discussed above is illustrated in FIG. 11. Hardware, firmware, software or a combination thereof may be used to perform the various steps and operations described herein. The processing device 1100 of FIG. 11 is an exemplary computing structure that may implement any of the processes and methods discussed above or combinations of them.

The exemplary processing device 1100 suitable for performing the activities described in the exemplary embodiments may include server 1101. Such a server 1101 may include a central processor unit (CPU) 1102 coupled to a random access memory (RAM) 1104 and/or to a read-only memory (ROM) 1106. ROM 1106 may also be other types of storage media to store programs, such as programmable ROM (PROM), erasable PROM (EPROM), etc. Processor 1102 may communicate with other internal and external components through input/output (I/O) circuitry 1108 and bus 1110 to provide control signals and the like. For example, processor 1102 may communicate with appropriate valves of the source elements for controlling the air pressure inside each source element. Processor 1102 carries out a variety of functions as are known in the art, as dictated by software and/or firmware instructions.

Server 1101 may also include one or more data storage devices, including disk drives 1112, CD-ROM drives 1114, and other hardware capable of reading and/or storing information, such as a DVD, etc. In one embodiment, software for carrying out the above-discussed steps may be stored and distributed on a CD-ROM 1116, removable media 1118 or other form of media capable of storing information. The storage media may be inserted into, and read by, devices such as the CD-ROM drive 1114, disk drive 1112, etc. Server 1101 may be coupled to a display 1120, which may be any type of known display or presentation screen, such as LCD, plasma displays, cathode ray tubes (CRT), etc. A user input interface 1122 is provided, including one or more user interface mechanisms such as a mouse, keyboard, microphone, touch pad, touch screen, voice-recognition system, etc.

Server 1101 may be coupled to other computing devices, such as the equipment of a vessel, via a network. The server

may be part of a larger network configuration as in a global area network (GAN) such as the Internet **1128**, which allows ultimate connection to the various landline and/or mobile client/watcher devices.

As also will be appreciated by one skilled in the art, the exemplary embodiments may be embodied in a wireless communication device, a telecommunication network, as a method or in a computer program product. Accordingly, the exemplary embodiments may take the form of an entirely hardware embodiment or an embodiment combining hardware and software aspects. Further, the exemplary embodiments may take the form of a computer program product stored on a computer-readable storage medium having computer-readable instructions embodied in the medium. Any suitable computer-readable medium may be utilized, including hard disks, CD-ROMs, digital versatile discs (DVD), optical storage devices or magnetic storage devices such as a floppy disk or magnetic tape. Other non-limiting examples of computer-readable media include flash-type memories or other known types of memories.

The disclosed exemplary embodiments provide a source array, sub-array and source element capable of boosting an energy generated in the 0.1 to 10 Hz range. It should be understood that this description is not intended to limit the invention. On the contrary, the exemplary embodiments are intended to cover alternatives, modifications and equivalents, which are included in the spirit and scope of the invention as defined by the appended claims. Further, in the detailed description of the exemplary embodiments, numerous specific details are set forth in order to provide a comprehensive understanding of the claimed invention. However, one skilled in the art would understand that various embodiments may be practiced without such specific details.

Although the features and elements of the present exemplary embodiments are described in the embodiments in particular combinations, each feature or element can be used alone without the other features and elements of the embodiments or in various combinations with or without other features and elements disclosed herein.

This written description uses examples of the subject matter disclosed to enable any person skilled in the art to practice the same, including making and using any devices or systems and performing any incorporated methods. The patentable scope of the subject matter is defined by the claims, and may include other examples that occur to those skilled in the art. Such other examples are intended to be within the scope of the claims.

What is claimed is:

**1.** A source element comprising:

a housing;

a partitioning element placed inside the housing and configured to split the housing in a closed chamber and an opened chamber;

a valve located inside the housing and in fluid communication with the closed chamber and configured to supply high-pressure air to the closed chamber to make the partitioning element oscillates; and

a controller located inside the housing and configured to control the valve to fluidly connect (1) a high-pressure source to the closed chamber and (2) a low-pressure source to the closed chamber, wherein an oscillation of the partitioning element generates low-frequency seismic waves.

**2.** The source element of claim **1**, wherein the closed chamber is isolated by the partitioning element from an ambient while the opened chamber freely communicates with the ambient.

**3.** The source element of claim **1**, wherein the valve is directly connected to the high-pressure source and to the low pressure source.

**4.** The source element of claim **1**,

wherein the controller and the valve are located in a nose of the source element.

**5.** The source element of claim **1**, further comprising:

a diverter connected to the opened chamber and configured to divert water exiting the opened chamber from a horizontal direction to a radial direction.

**6.** The source element of claim **1**, further comprising:

a first stopping element located inside the closed chamber; and

a second stopping element located inside the opened chamber,

wherein the first and second stopping elements are configured to limit a movement of the partitioning element.

**7.** The source element of claim **1**, wherein the partitioning element has a circumference fixedly attached to the housing.

**8.** The source element of claim **7**, wherein the partitioning element is a flexible membrane.

**9.** The source element of claim **1**, wherein the partitioning element is a piston.

**10.** A method for generating low-frequency seismic energy, the method comprising:

deploying in water a source element that includes a housing split into a closed chamber and an opened chamber by a partitioning element;

supplying compressed air through a valve located inside the housing, to the closed chamber so that the partitioning element moves toward the opened chamber;

generating low-frequency seismic waves by moving the partitioning element; and

venting the closed chamber to a low-pressure source for returning the partitioning element,

wherein a controller located inside the housing controls the valve to fluidly connect (1) a high-pressure source to the closed chamber and (2) the low-pressure source to the closed chamber.
